

The following is to acquaint you with of some lesser known properties of exponentials and logarithms

1.8.1 Backsides of exponentials

- (a) Follow zig-zag scheme shown at the beginning of Lect. 11 to make plots of exponential  $y=e^x$  at as many integer points  $x= -2, -1, 0, 1, 2,..$  as is practical on full page graph paper provided online or in lab. Then add to the plot precise half-way points  $x= -2.5, -1.5, -0.5, etc...$  as is practical. Show how a plot of  $y=log_e x$  function is obtained from the graph
- (b) By algebra or geometry find tangent lines and their slope at integer points  $x=-2, -1, 0, 1, 2,..$  (This is equivalent to solving the part (c) of this exercise.)
- (c) As a roller-coaster car moves down a track  $y=e^x$  it shines one laser headlight beam along the track and another droplight beam vertically downward so both make spots on baseline  $y=0$ . Find the distance between spots as function of  $x$ .

1.8.2 Sophomore-Physics-Earth

- (a) Follow the zig-zag scheme in Lect. 11 (or in Fig. 8.5 and 8.7 of text) to construct the potential and force curves of the Ideal Uniform Density Earth inside ( $PE(x)=kx^2/2+PE(0)$ ) and outside ( $PE(x)=-x^{-1}$ ).
- (b) On graph show focal point, latus-radius , and directrix of the inside PE parabola. Draw as accurately as possible the parabola's circle of curvature contacting it at  $x=0$ .
- (c) Draw a "kite" (see Fig. 8.4 in text) tangent to parabola at  $x=l$  and another tangent at  $x=1/2$ .

1.8.3 Tunnels to UK (5600 miles as an earthworm crawls) are shown below. One high-road is a direct route. A low-road turns at the Earth center. (Travel and turn-around are assumed frictionless and survivable.)

- (a) What is the time for each trip? Discuss using geometry or algebra arguments.

(a) Hi-road & low-road

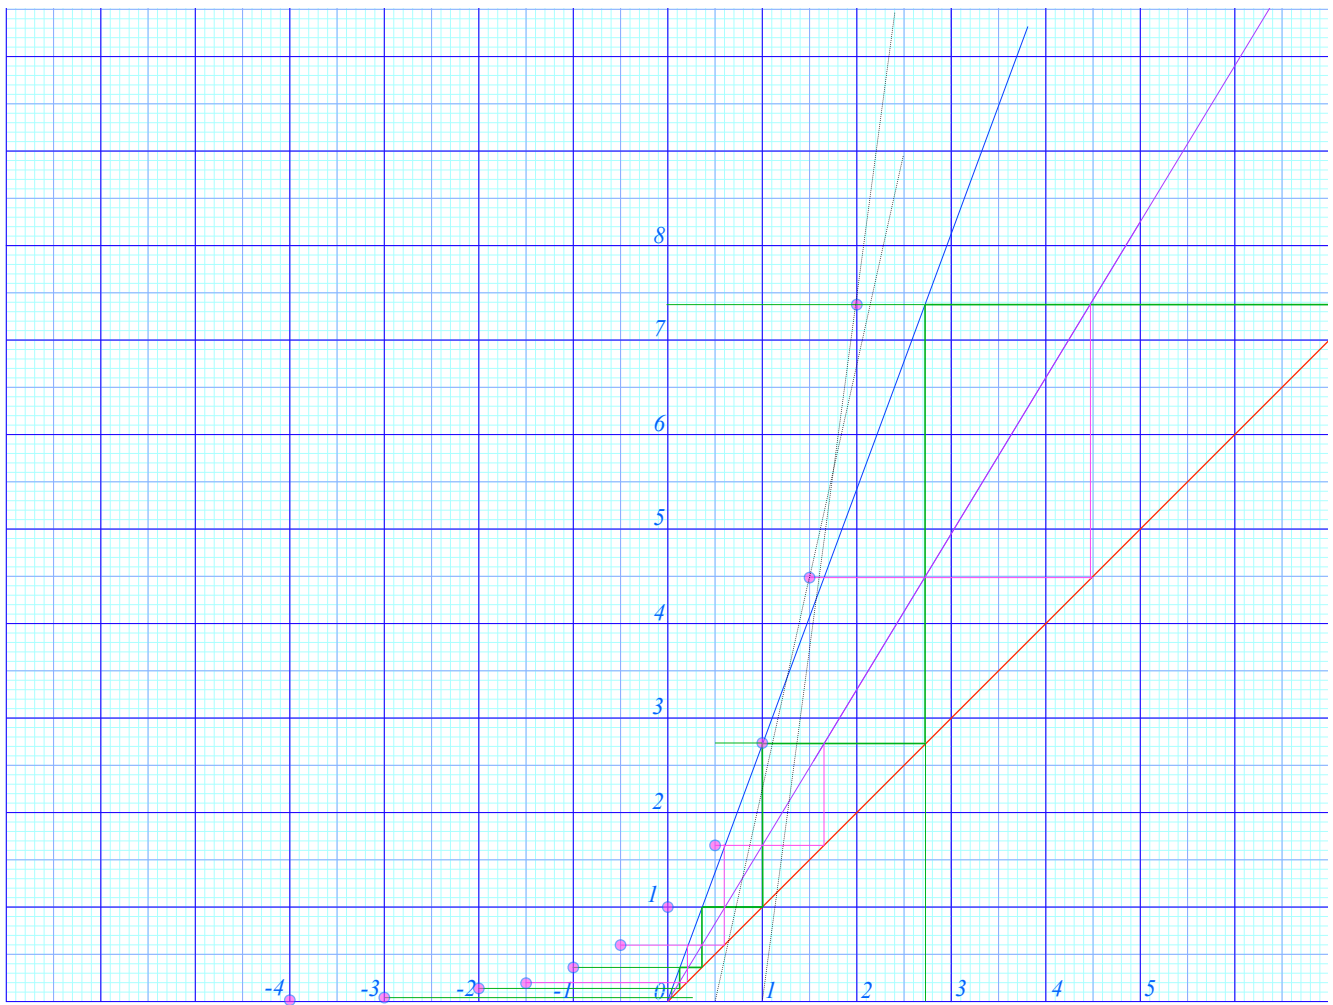

(b) Lots of roads

- (b) Assume cars in subway tunnels depart Ark. at time  $t=0$  as indicated above. Describe curve (thru dots shown) locating car positions at a later mid-trip time  $t$  before arrival and at arrival. (Thales geometry of circular chords may help. Recall superbball figure 6.1 in text.)
- (c) What if the half-way turn-around point is above the Earth-center. Is trip quicker or slower?

(a) Follow zig-zag scheme shown at the beginning of Lect. 11 to make plots of exponential  $y=e^x$  at as many integer points  $x= -2, -1, 0, 1, 2,..$  as is practical on full page graph paper provided online or in lab. Then add to the plot precise half-way points  $x= -2.5, -1.5, -0.5, etc...$  as is practical. Show how a plot of  $y=\log_e x$  function is obtained from the graph

*Each slope line intersects  $y=0$  exactly  $-1$  unit distance from their  $x$ -coordinate point.*

*If the graph is expanded it clearly shows that there is unit distance ( $\Delta x=1$ ) between  $x$ -axis intersections of any tangent to point  $(x, y=e^x)$  and the vertical line  $x=x_1$  going thru that point. Quite remarkable! All tangents to  $y=e^x$  have unit footprints.*

*Exercise 1.8.3.* Tunnels to UK (5600 miles away as an earthworm crawls) are shown below. One high-road is a direct route. The other low-road turns around at the Earth center. Travel and turn-around are assumed frictionless and survivable. (a) How long is each trip? Discuss. **Both the same.**

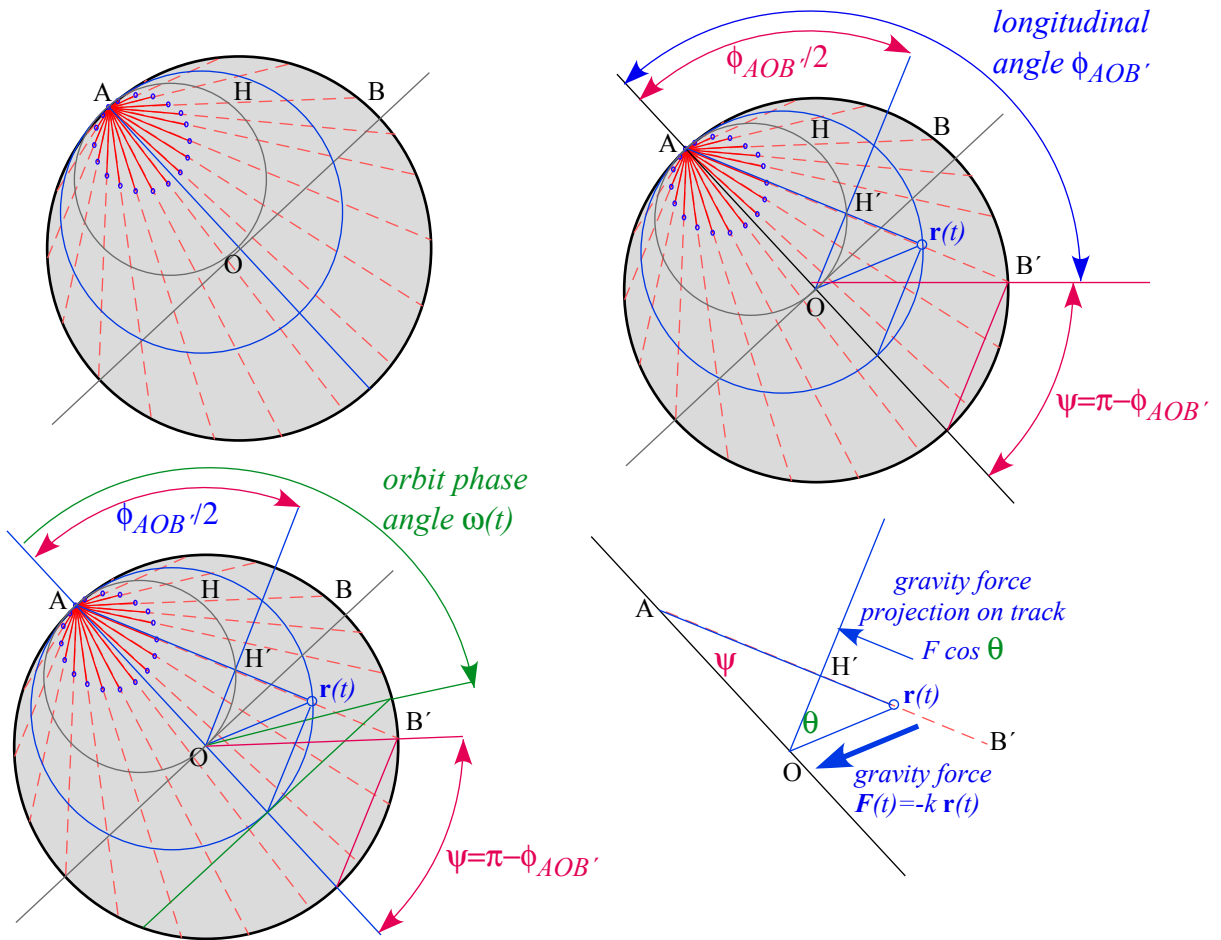

(a) *Hi-road & low-road*

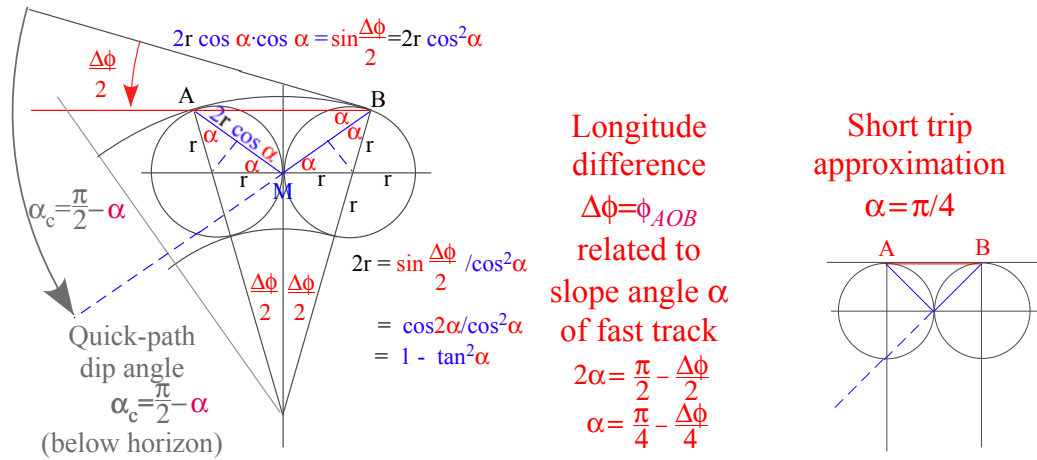

(b) *Lots of roads*

(b) A network of subways leaving Ark. at time  $t=0$ . What curve (like the dots) describe each moment? Each is on a **circle** at distance  $r_A = D \cos \theta$  from A with  $D = R_{\text{earth}}(1 - \cos \omega_{\text{earth}} t)$ .  $\theta$  is subway polar angle and  $\pi / \omega_{\text{earth}} = 42$  minutes is the one-way surface-to-surface trip on each  $\theta$  path having length  $L = R_{\text{earth}} \cos \theta$ .

(c) What if the half-way turn-around point is above the Earth-center. Is trip quicker or slower? There is a point nearly midway between the bend at Earth-center and the center of the straight Ark. to U.K. track where the bend should be to achieve a minimum travel time and shorter than the others'.

The more difficult problem of deep-V-tunnel global travel is solved similarly, but a geometric solution sketched below is quick (once you see the trick!). The trick is to imagine a pencil of competing tunnels going out from both point A and point B so that the trial runs form two expanding circles that finally touch on a tangent that bisects the A-to-B longitude angle  $\phi_{AOB} = \Delta\phi$ . We find the angle  $\alpha = \pi/4 - \Delta\phi/4$  between shortest path and *quickest* path. It approaches  $\alpha = 45^\circ$  in the local limit  $\Delta\phi \rightarrow 0$ . The *AMB* vertex angle is  $\phi_{AMB} = \pi/2 + \phi_{AOB}/2$  and approaches a local  $90^\circ$  limit. Half the *AMB* vertex angle is  $\phi_{AMB}/2 = \pi/2 - \alpha = \alpha_c$  (compliment of  $\alpha$ ) that is also horizon dip angle between the horizon and the quickest path. For short trips:  $\alpha = \alpha_c = 45^\circ$ . For longer trips:  $\alpha < 45^\circ$  and  $\alpha_c > 45^\circ$ .

Each circle diameter  $D = 2r$  (in units of Earth radius  $R_\oplus$ ) expands as  $D = l \cdot \cos \theta$  where  $\theta = \omega t$  is the circular orbit subtended by projecting the diameter point to the Earth circle. Travel time T is proportional to angle  $\theta$  with  $\theta = \pi$  corresponding to 42 minutes of a half-circle orbit and  $\theta = \pi/2$  to 21 min. (Going half-way between A and B by the straight tunnel takes 21 minutes.)
